Abstract

We derive the planar large N non-supersymmetric background of the quantum mechanical hamiltonian of two hermitean matrices coupled via a Yang-Mills interaction, in terms of the density of eigenvalues of one of the matrices. This background satisfies an implicit non linear integral equation, with a perturbative small coupling expansion and a solvable large coupling solution, which is obtained. The energy of system and the expectation value of several correlators are obtained in this strong coupling limit. They are free of infrared divergences.

1 Introduction

The study of multi-matrix models¹, and particularly their large N limit [1], is of great interest. It is well known, for instance, that the large N limit of their description of D0 branes [2] has been conjectured to provide a definition of M theory [3]. In the context of the AdS/CFT duality [4], [5], [6], due to supersymmetry and conformal invariance, correlators of supergravity and 1/2 BPS states reduce to calculation of free matrix model overlaps [7], [8] or consideration of related matrix hamiltonians [9]. For stringy states, in the context of the BMN limit [10] and $\mathcal{N} = 4$ SYM, similar considerations apply [11], [12], [13]. A plane-wave matrix theory [14] is related to the $\mathcal{N} = 4$ SYM dilatation operator [15]. Recently, multi-matrix, multi-trace operators with diagonal free two point functions have been identified [16], [17]. In earlier works [18], [19], [20] it has been argued that QCD can be reduced to a finite number of matrices with quenched momenta.

In this communication we will consider the quantum mechanics of two hermitean matrices with harmonic potentials, interacting through a standard Yang-Mills quartic potential.

We will use the approach, first developed in [21], of treating one of the matrices, which generates the large N planar background, in a coordinate representation, and the other in a creation/annihilation basis. This was done in the context of 1/2 BPS states and a dual free harmonic Hamiltonian [8], [9] with the matrix generating the background being the holomorphic component of a complex matrix. A precise phase space identification between the collective density description of the dynamics of this matrix [22], and the droplet description of the LLM [23] metric is obtained [21]. The generalization of this approach to include g_{YM} interactions was developed in [24]. By considering the planar background generated by one of the two Hermitean matrices, further properties of the spectrum were established in [25].

In [21], [24] and [25], a supersymmetric setting was always assumed, allowing one to consistently neglect normal ordering terms. As a result, the planar background is harmonic, and g_{YM} independent.

In this communication we explore the consequences of not requiring supersymmetry, and establish a g_{YM} dependent density description of the planar large N limit of the system. The communication is organized as follows: in

¹By matrix models we mean integrals over matrices or the quantum mechanics of matrix valued degrees of freedom

Section 2, the hamiltonian of the two interacting harmonic matrices is introduced. It is shown how a Bogoliubov transformation brings the hamiltonian to a form quadratic in the creation/annihilation oscillators of one of the matrices, with frequencies having a square root dependence on the eigenvalues of the other matrix [24]². The sector of the Hamiltonian contributing to the planar large N background is identified. In Section 3, the planar background, in terms of the density of one the matrices, is obtained implicitly through a non-linear integral equation. In Section 4, the perturbative expansion in $\lambda = g_{YM}^2$ is described, and the first order correction obtained and shown to agree with perturbation theory. In section 5, the strong coupling limit of the background is obtained explicitly. In Section 6, it is argued that this strong coupling limit is indeed the background for two free hermitean matrices interacting through the Yang-Mills potential. This solution is free of infrared divergences. Section 7 is reserved for a summary and discussions.

2 Model Hamiltonian and planar large N sector

We consider the quantum mechanical hamiltonian

$$\hat{H} \equiv \frac{1}{2}Tr(P_1^2) + \frac{w^2}{2}Tr(X_1^2) + \frac{1}{2}Tr(P_2^2) + \frac{w^2}{2}Tr(X_2^2) - g_{YM}^2 Tr([X_1, X_2][X_1, X_2]), \quad (1)$$

where X_1 and X_2 are two $N \times N$ hermitean matrices, and P_1 and P_2 their conjugate momenta, respectively.

One can think of (1) as associated with two of the six Higgs scalars of the bosonic sector of $\mathcal{N} = 4$ SYM, in the leading Kaluza Klein compactification on $S^3 \times R$. The harmonic potential results from the coupling to the curvature of the manifold. It should be borne in mind that we do not require supersymmetry. Alternatively, compactification of QCD_{2+1} on a sphere results in a similar hamiltonian.

We will follow the approach first suggested in [21] of treating one of matrices, X_1 , in coordinate space and exactly (in the large N limit), and the other, X_2 , in a creation/annihilation basis. Letting

²See also [26]

$$X_2 \equiv \frac{1}{\sqrt{2w}}(A_2 + A_2^\dagger) \quad P_2 = -i\sqrt{\frac{w}{2}}(A_2 - A_2^\dagger) \quad (2)$$

the hamiltonian (1) takes the form

$$\begin{aligned} \hat{H} &= \frac{1}{2}\text{Tr}(P_1^2) + \frac{w^2}{2}\text{Tr}(X_1^2) + w\text{Tr}(A_2^\dagger A_2) + N^2 \frac{w}{2} \\ &- \frac{g_{YM}^2}{2w}\text{Tr}(2[X_1, A_2^\dagger][X_1, A_2] + [X_1, A_2]^2 + [X_1, A_2^\dagger]^2) \\ &+ \frac{g_{YM}^2 N}{w}\text{Tr}(X_1^2) - \frac{g_{YM}^2}{w}(\text{Tr}(X_1))^2 \end{aligned} \quad (3)$$

As the interaction is quadratic in the oscillators, one can perform a Bogoliubov transformation

$$(V^\dagger A_2 V)_{ij} = \cosh(\phi_{ij})B_{ij} - \sinh(\phi_{ij})B_{ij}^\dagger \quad (4)$$

with

$$\tanh(2\phi_{ij}) = \frac{\frac{g_{YM}^2}{w}(\lambda_i - \lambda_j)^2}{w + \frac{g_{YM}^2}{w}(\lambda_i - \lambda_j)^2}, \quad (5)$$

where the λ_i 's are the eigenvalues of the matrix X_1 and V is the unitary matrix that diagonalizes X_1 . Then (3) takes the form

$$\hat{H} = \frac{1}{2}\text{Tr}(P_1^2) + \frac{w^2}{2}\text{Tr}(X_1^2) + \sum_{i,j=1}^N \sqrt{w^2 + 2g_{YM}^2(\lambda_i - \lambda_j)^2} \quad (B_{ij}^\dagger B_{ji} + \frac{1}{2}). \quad (6)$$

We are interested in the leading large N configuration of the system. In the $B, B^\dagger$ sector of the theory, states with non zero B quanta lead to excited states and spectra, which contributions which are subleading in $\frac{1}{N}$. The only contribution to the large N ground state configuration comes from the zero point energies of the $B, B^\dagger$ oscillators, and we are therefore led to the Hamiltonian:

$$\hat{H}_0 = \frac{1}{2}\text{Tr}(P_1^2) + \frac{w^2}{2}\text{Tr}(X_1^2) + \frac{1}{2} \sum_{i,j=1}^N \sqrt{w^2 + 2g_{YM}^2(\lambda_i - \lambda_j)^2} \quad (7)$$

3 A self consistent non linear integral equation for the large N background

The Hamiltonian (7) describes the dynamics of a single hermitean matrix, and the large N background can be described in terms of the density of eigenvalues,

$$\phi(x) = \sum_i \delta(x - \lambda_i),$$

as the minimum of the cubic collective field effective potential [22]

$$\begin{aligned} V_{eff} = & \frac{\pi^2}{6} \int dx \phi^3(x) + \frac{w^2}{2} \int dx \phi(x) x^2 - \mu \left(\int dx \phi(x) - N \right) \\ & + \frac{1}{2} \int dx \int dy \sqrt{w^2 + 2g_{YM}^2(x-y)^2} \phi(x) \phi(y), \end{aligned} \quad (8)$$

where the Lagrange multiplier μ enforces the constraint $\int dx \phi(x) = N$. To exhibit explicitly the N dependence, we rescale

$$x \rightarrow \sqrt{N} \quad \phi(x) \rightarrow \sqrt{N} \phi(x) \quad \mu \rightarrow N\mu \quad (9)$$

and obtain

$$\begin{aligned} V_{eff} = & N^2 \left[\frac{\pi^2}{6} \int dx \phi^3(x) + \frac{w^2}{2} \int dx \phi(x) x^2 - \mu \left(\int dx \phi(x) - 1 \right) \right. \\ & \left. + \frac{1}{2} \int dx \int dy \sqrt{w^2 + 2\lambda(x-y)^2} \phi(x) \phi(y) \right] \end{aligned} \quad (10)$$

where $\lambda = g_{YM}^2 N$ is the usual 't Hooft's coupling.

As $N \rightarrow \infty$, the large N background configuration minimizes (10) and it satisfies:

$$\pi^2 \phi_0^2(x) = 2\mu - w^2 x^2 - 2 \int dy \sqrt{w^2 + 2\lambda(x-y)^2} \phi_0(y) \quad (11)$$

4 Perturbative expansion

When $\lambda = 0$, (11) reduces to the well known Wigner distribution:

$$\pi\phi_0(x) = \sqrt{2\mu - 2w - w^2x^2} = \sqrt{2w - w^2x^2}, \quad |x| \leq x_0 = \sqrt{\frac{2}{w}} \quad (12)$$

with the identification $\mu = 2w$ being enforced by the constraint. Given that $\frac{2}{\pi} \int_0^{x_0} dx x^2 \sqrt{2w - w^2x^2} = \frac{1}{2w}$ it is straightforward to obtain

$$\begin{aligned} E_0 &= N^2 \left[\frac{\pi^2}{6} \int dx \phi_0^3(x) + \frac{w^2}{2} \int dx \phi_0(x) x^2 + \frac{w}{2} \left(\int dx \phi_0(x) \right)^2 \right] \\ &= N^2 \left[\frac{w}{4} + \frac{w}{4} + \frac{w}{2} \right] = N^2 w \end{aligned} \quad (13)$$

as it should, the ground state energy being simply the sum of the zero point energies of two (N^2) free oscillators.

To next order, we assume that the background remains even ($\int dx x \phi_0 = 0$) and obtain from (11)

$$\pi^2 \phi_0^2(x) = 2\mu - 2w - \frac{2\lambda}{w} \omega_2 - (w^2 + \frac{2\lambda}{w}) x^2, \quad \omega_2 = \int x^2 \phi_0(x) \quad (14)$$

Therefore, to this order, the background remains of the Wigner type³:

$$\pi\phi_0(x) = \sqrt{2\bar{w} - \bar{w}^2 x^2}, \quad |x| \leq x_0 = \sqrt{\frac{2}{\bar{w}}} \quad \bar{w}^2 = w^2 + \frac{2\lambda}{w} \quad (15)$$

It follows that

$$E_0 = N^2 \left[\frac{\bar{w}}{4} + \frac{\bar{w}}{4} + \frac{w}{2} \right] = N^2 \left[w + \frac{\lambda}{2w^2} + \dots \right].$$

As an example of an equal time correlator, one straightforwardly obtains:

$$\langle Tr X_1^2 \rangle = N^2 \int dx x^2 \phi_0 = N^2 \frac{1}{2\bar{w}} = N^2 \left[\frac{1}{2w} - \frac{\lambda}{2w^4} + \dots \right] \quad (16)$$

These results are in agreement with perturbation theory.

³ μ is suitably adjusted.

Planar expectation values of correlators involving the X_2 coordinate can also be calculated. This requires expressing X_2 in terms of the B oscillators using (4) and (5), and then reducing the correlator to a correlator involving the X_1 matrix only, with the use of the B oscillator commutation relations. Because the $B, B^\dagger$ sector is quadratic in the oscillators, this can lead to highly nontrivial non-perturbative results. For instance,

$$\begin{aligned} \langle Tr X_2^2 \rangle &= \frac{1}{2w} \sum_{ij} \cosh(2\phi_{ij}) - \sinh(2\phi_{ij}) = \frac{1}{2} \sum_{ij} \frac{1}{\sqrt{w^2 + 2g_{YM}^2(\lambda_i - \lambda_j)^2}} \\ &= \frac{N^2}{2} \int dx \int dy \frac{\phi_0(x)\phi_0(y)}{\sqrt{w^2 + 2\lambda(x-y)^2}} = \frac{N^2}{2w} \left(1 - \frac{\lambda}{w^3} + \dots\right) \end{aligned} \quad (17)$$

This equation shows how, to order λ , the $X_1 \leftrightarrow X_2$ symmetry of planar correlators is satisfied, despite the asymmetric treatment of the two coordinates in the approach followed in this communication. If we require, as we must, that this $X_1 \leftrightarrow X_2$ symmetry is exact, then (16) and (17) establish a highly non-trivial property of the planar background.

Of great physical interest is to obtain the states which correspond to the spectrum of the system. This can be done in principle using the framework developed in [21], [24] and [25], but is beyond the scope of this communication.

5 Strong coupling solution

We consider now (11) and (10) as $\lambda \rightarrow \infty$:

$$\pi^2 \phi_0^2(x) = 2\mu - 2\sqrt{2\lambda} \int dy |x-y| \phi_0(y) \quad (18)$$

$$E_0 = N^2 \left[\frac{\pi^2}{6} \int dx \phi_0^3(x) + \frac{\sqrt{2\lambda}}{2} \int dx \int dy |x-y| \phi_0(x) \phi_0(y) \right] \quad (19)$$

We find it useful to introduce

$$f(x) = \sqrt{2\lambda} \int dy |x-y| \phi_0(y), \quad \pi^2 \phi_0^2(x) = 2(\mu - f(x)) \quad (20)$$

which satisfies

$$f(x) = \frac{\sqrt{2\lambda}}{\pi} \int dy |x - y| \sqrt{2(\mu - f(y))}. \quad (21)$$

As it was the case in perturbation theory, we assume that $\phi_0(x)$ remains an even, single cut function defined in the interval $[-x_0, x_0]$. To show that this is a consistent ansatz, we note that then:

$$f(x) = \sqrt{2\lambda} \left(|x| \int_{-|x|}^{|x|} \phi_0(y) dy + 2 \int_{|x|}^{x_0} \phi_0(y) y dy \right). \quad (22)$$

Hence $f(x)$ is also even, establishing the consistency of the ansatz. Using

$$\partial_x^2 |x - y| = 2\delta(x - y),$$

equation (21) becomes⁴

$$\partial_x^2 f(x) = \frac{4\sqrt{\lambda}}{\pi} \sqrt{\mu - f(x)} \quad (23)$$

This can be integrated in the usual way, to yield:

$$\frac{1}{2}(\partial_x f)^2 + \frac{8\sqrt{\lambda}}{3\pi}(\mu - f(x))^{\frac{3}{2}} = e \quad (24)$$

The "energy" constant is fixed by the condition $\partial_x f(0) = 0$. Denoting $f(0) \equiv f_0$ one obtains

$$\frac{df}{dx} = \frac{4\lambda^{\frac{1}{4}}}{\sqrt{3\pi}} \sqrt{(\mu - f_0)^{\frac{3}{2}} - (\mu - f(x))^{\frac{3}{2}}} \quad (25)$$

The normalization condition

$$1 = \int_{-x_0}^{x_0} dx \phi_0(x) = 2 \int_0^{x_0} dx \phi_0(x) = 2 \int_{f_0}^{\mu} df \frac{\phi_0(f)}{\frac{df}{dx}}$$

fixes

$$(\mu - f_0)^{\frac{3}{2}} = \left(\frac{3\pi}{8}\right) \lambda^{\frac{1}{2}},$$

⁴ ϕ_0^2 satisfies a very similar equation.

and hence (25) takes the form:

$$\frac{df}{dx} = \sqrt{2\lambda} \sqrt{1 - \left(\frac{\mu - f(x)}{\mu - f_0} \right)^{\frac{3}{2}}}. \quad (26)$$

We will not need to invert (26) and obtain $f(x)$ explicitly, as all results presented in this communication will be expressed in terms of known definite integrals.

Of particular interest is the large N ground state energy. From (19) and (20) this can be written as

$$E_0 = N^2 \left[\frac{\pi^2}{6} \int dx \phi_0^3(x) + \frac{1}{2} \int dx f(x) \phi_0(x) \right] = N^2 \left[\frac{\mu}{2} - \frac{\pi^2}{12} \int dx \phi_0^3(x) \right] \quad (27)$$

One needs to know μ , or f_0 , independently. From (22), one obtains

$$f_0 = \sqrt{2\lambda}x_0 - (\mu - f_0) \quad \mu = \sqrt{2\lambda}x_0.$$

From (26) one obtains

$$\sqrt{2\lambda}x_0 = (\mu - f_0) \int_0^1 \frac{dz}{\sqrt{1 - (1 - z)^{\frac{3}{2}}}} = 2(\mu - f_0) \int_0^1 \frac{tdt}{\sqrt{1 - t^3}}.$$

Also

$$\frac{\pi^2}{12} \int dx \phi_0^3(x) = \frac{1}{6}(\mu - f_0) \int_0^1 dz \sqrt{1 - (1 - z)^{\frac{3}{2}}} = \frac{1}{3}(\mu - f_0) \int_0^1 t dt \sqrt{1 - t^3}.$$

These integrals are tabulated [27], and are finite. Therefore

$$E_0 = N^2 \left[\frac{6}{7} \left(\frac{3\pi}{8} \right)^{\frac{2}{3}} \int_0^1 \frac{tdt}{\sqrt{1 - t^3}} \lambda^{\frac{1}{3}} \right] = N^2 \left[\frac{9}{14} \left(\frac{\sqrt{3}}{4\pi} \right)^{\frac{1}{3}} \left(\Gamma\left(\frac{2}{3}\right) \right)^3 \lambda^{\frac{1}{3}} \right] \quad (28)$$

Similarly to the weak coupling case, we consider the correlator

$$\langle Tr X_1^2 \rangle = N^2 \int dx x^2 \phi_0 = 2N^2 \int_{f_0}^{\mu} x^2(f) \frac{\phi_0(f)}{\frac{df}{dx}} df$$

By a sequence of integrations by parts, we obtain

$$\begin{aligned}
\langle \text{Tr} X_1^2 \rangle &= N^2 \left[-\frac{\mu^2}{2\lambda} + \frac{2}{\sqrt{2\lambda}} \int_{f_0}^{\mu} \frac{f}{\frac{df}{dx}} df \right] \\
&= 2 N^2 \left(\frac{3\pi}{8} \right)^{\frac{4}{3}} \lambda^{-\frac{1}{3}} \left[\left(\int_0^1 \frac{t dt}{\sqrt{1-t^3}} \right)^2 - \frac{2}{5} \int_0^1 \frac{dt}{\sqrt{1-t^3}} \right] \\
&= \frac{N^2}{\pi 2^{\frac{1}{3}} \sqrt{3}} \left(\frac{3\pi}{8} \right)^{\frac{4}{3}} \lambda^{-\frac{1}{3}} \left[\frac{3\sqrt{3}}{\pi} \left(\Gamma\left(\frac{2}{3}\right) \right)^6 - \frac{2}{5} \left(\Gamma\left(\frac{1}{3}\right) \right)^3 \right]
\end{aligned} \tag{29}$$

6 Interacting massless matrices

The results of the previous section could have also been obtained by taking the limit $w \rightarrow 0$ of the planar hamiltonian (7). It is therefore relevant to discuss the relevance of these results for the system

$$\hat{H} \equiv \frac{1}{2} \text{Tr}(P_1^2) + \frac{1}{2} \text{Tr}(P_2^2) - g_{YM}^2 \text{Tr}([X_1, X_2][X_1, X_2]), \tag{30}$$

which results from the dimensional reduction of massless Higgs or non abelian vector potentials. The hamiltonian (30) has a single dimensionful parameter, $\lambda = g_{YM}^2 N$, and therefore all observable quantities should depend only on well defined powers of λ . However, as is well known, perturbation theory is plagued with infrared divergences. In this context, w can be thought of as a standard “mass” regulator.

The results of the previous section are therefore remarkable, as they are finite and free of any infrared divergences, and depend only on the appropriate power of λ which is expected from dimension considerations.

It has already been pointed out the expression (7) has a smooth $w \rightarrow 0$ limit. The only place where this limit is potentially ill defined is in the transformation (4), where w has to be kept finite, if small, to ensure that the transformation is canonical. However, once the Bogoliubov transformation is implemented and the Hamiltonian (1) is recast in the form (6), its $w \rightarrow 0$ limit should provide a correct description of the system (30).

We are confident that indeed the results of the previous section, which are finite and free of any infrared divergences, are the planar energy and correlator of (30). This provides another explicit confirmation of the expectation that strong coupling dynamics, appropriately resummed through the large N limit, is free of infrared divergences.

7 Summary and discussion

In this communication, we obtained the large N planar background of two hermitean matrices, in an harmonic potential, interacting through a Yang-Mills potential, in terms of the density of eigenvalues of one of the matrices. This background is shown to satisfy a self-consistent g_{YM} dependent integral equation. This integral equation has both a weak and a strong coupling expansion. The weak coupling expansion of the background is described and shown to be in agreement with perturbation theory. For strong coupling, we show that the background satisfies a non-linear differential equation, with a solution which is described. The planar ground state energy and examples of correlators are obtained and shown to be finite. We argue that this is the full planar solution of the hamiltonian of two “massless” matrices (i.e., without the harmonic potential, or in the zero curvature limit) with a Yang-Mills interaction.

It may be tempting to associate the background obtained in this communication with a non-supersymmetric g_{YM} deformation of the “droplet” description of 1/2 BPS states [8], [9], [23]. It should be remembered, though, that the matrix description of the geometry is a phase space description. The hermitean matrix associated with the droplet corresponds to the holomorphic restriction of a complex matrix [21], unlike the choice made in this communication⁵

On the other hand, as pointed out at the end of Section 4, by exploiting the $X_1 \leftrightarrow X_2$ symmetry of the system, we can write from (17) and as $\lambda \rightarrow \infty$,

$$\langle Tr X_1^2 \rangle = \langle Tr X_2^2 \rangle = \frac{1}{2} \sum_{ij} \frac{1}{\sqrt{2g_{YM}^2} |\lambda_i - \lambda_j|}. \quad (31)$$

With a physical interpretation of the eigenvalues as coordinates of a system of $D0$ ’s, the feature of (29) that its “size” becomes small but finite for large λ can be interpreted as resulting from the “back-reaction” exhibited on the right hand side of (31).

Clearly, it would be very interesting to examine this question further. However, at the very least, the background identified in this article is a g_{YM} deformation of the Wigner distribution associated with harmonic potentials, with a well defined strong coupling limit.

⁵As an example of how the kinetic energy operator of the hamiltonian is changed in this case, see [28].

8 Acknowledgements

One of us (J.P.R.) would like to thank the High Energy Theory Group of Brown University for their hospitality during several research visits over the last two years, which allowed for concentrated effort leading to some of the ideas presented in this communication. We thank Antal Jevicki and Robert de Mello Koch for reading the manuscript, comments and discussion.
